# Charting new frontiers in artificial intelligence for antibiotic design

Moderator: Akhila Kosaraju Phare Bio

Jonathan Stokes McMaster University

Kurt Thorn Arrepath, Inc.

## **Jonathan Stokes**

Jonathan Stokes is an assistant professor in the Department of Biochemistry and Biomedical Sciences at McMaster University, Canada. He is also co-founder and Chief Scientific Officer of Stoked Bio.

His research group focuses on the development and implementation of machine learning methods for drug discovery and design. They currently work on discovering novel antibiotics to overcome drug-resistant bacteria and new molecules to treat an aggressive form of brain cancer called glioblastoma.

Jonathan received his PhD in antimicrobial chemical biology in 2016 from McMaster University. From 2017 to 2021, he was a Banting postdoctoral fellow at the Broad Institute of MIT and Harvard in the USA.

#### How should we be using AI to help us fight superbugs?

Jon Stokes Assistant Professor Department of Biochemistry and Biomedical Sciences McMaster University

#### We are in an antibiotic discovery void

Al allows us to explore vast chemical spaces for new useful chemical matter

High throughput screening = millions of molecules (<1% in vitro success rate)

Al models > billions of molecules (>10% in vitro success rate)

Acinetobacter baumannii is a challenging nosocomial gram-negative pathogen

We performed a screen of ~7,500 diverse molecules against A. baumannii

Using graph neural networks for antibiotic prediction against A. baumannii

## **Kurt Thorn**

Kurt Thorn is Chief Technology Officer at ArrePath, a biotech company that uses a combination of human intelligence and a cutting-edge AI/ML platform to discover and develop small molecule therapeutics to address significant unmet medical needs. Here, he leads efforts to develop tools to accelerate drug discovery for novel antibacterials.

Prior to this, Kurt was senior director of data science at Zymergen, a synthetic biology company. Before transitioning to industry, Kurt was a research fellow at Havard University and an associate professor at University of California, San Francisco (UCSF) and Director of the Nikon Imaging Center at UCSF.

Kurt has a PhD in biophysics from UCSF and received his bachelor's degree in chemistry from Princeton University.

# The AI for AMR Company

## Identifying Progressible Antibiotic Candidates Using Machine Learning-Guided Screening

Shilpa George, Kevin Hare, Graham Hone, Paul Lukacs, Kurt Thorn

## New approaches are needed to discover novel antibacterials

1.27 million deaths were caused by AMR worldwide in 2019

- Conventional (target-based) drug discovery approaches have largely failed to deliver new antibacterials, owing to the challenges of bacterial permeability and efflux (especially in Gramnegative bacteria).
- ArrePath is taking a three-pronged approach to address this problem:
  - 1. ML models to predict novel whole-cell active compounds
  - 2. Phenotypic screening of predicted whole cell active compounds
  - 3. Image-based phenotyping to identify novel mechanisms of action

## Antimicrobial resistance is a severe and growing problem

#### Novel Antibiotic classes

#### 1900 1910 1920 1930 1940 1950 1960 1970 1980 1990 2000 2010 2020

The Golden Age of antibiotic discovery

The Drought of antibiotic discovery

Pew Charitable Trust available at <u>https://wellcome.org/news/its-time-fix-antibiotic-market</u> Global burden of bacterial antimicrobial resistance in 2019: a systematic analysis, The Lancet, Jan 2022

## ArrePath's goal: Efficiently discover whole-cell active antibiotics with novel mechanisms of action

A

Focus on Gram-negative bacteria

## Hypothesis: ML models will learn target engagement, permeation, and efflux avoidance

#### Successful antibiotics must:

- Permeate the bacterial membrane(s) and cell wall
- Avoid efflux pumps
- Engage with the target

#### **Our Hypothesis:**

• A single ML model can learn chemical features associated with all three properties

#### Goal: maximize progressible hits by finding molecules that:

- 1. Kill bacteria
- 2. Don't kill mammalian cells
- 3. Have favorable medicinal chemistry features
- 4. Are chemically distinct from known antibacterial compounds

#### Modeling implications:

- Need models for *E. coli* activity and cytotoxicity that extrapolate well to new compounds
- Filter for unfavorable medicinal chemistry and PAINS
- Remove molecules structurally similar to commercial antibiotics

- There are an estimated 10<sup>33</sup> drug like molecules that can be made
- Commercial screening collections are ~5M compounds in size
- Goal of model is to identify the most active molecules in these collections – we don't need to predict an MIC, just an ordering.
- We want to maximize the amount and diversity of the compounds we can train our model on

**ARREPA** 

### Models are designed to prioritize compounds for screening

- Datasets are scaffold-split we evaluate model performance on Bemis-Murcko scaffolds different from those we train on
- Models are evaluated by how well they prioritize active molecules
- Virtual screening curves plot hits found as a function of library screened, if screened in the order ranked by the model

#### Scoring metrics:

- lift@X: 20% hits found at 1% screened compared to 1% from a random model → 20x lift
- Gini coefficient a function of area under the curve.
  0 = random; 100 = perfect

Bemis-Murcko scaffolds: The Properties of Known Drugs. 1. Molecular Frameworks. J. Med. Chem 1996

## Antibiotic activity can be predicted across strains

More data from diverse strains outperforms less data from identical strains

- Nearly all compounds active in WT *E. coli* are also active in permeabilized or efflux deficient strains
- Most (98%) of compounds are inactive in any strain.
- Mutant strain data improves WT activity prediction, even though most mutant-active compounds are inactive against WT.

0/ of actives also active in

	WT	Sol actives also activeNTtolCIpxC	
WT	100	84	86.2
tolC	9.3	100	30.6
ІрхС	24.3	78.6	100

Data from CO-ADD

Red: WT *E. coli* predicted with 400k cpds measured in *lptD E. coli* Blue: WT *E. coli predicted* with 500 cpds measured in WT *E. coli* 

CO-ADD: Blaskovich MAT, Zuegg J, Elliott AG, Cooper MA. Helping Chemists Discover New Antibiotics. ACS Infect Dis. American Chemical Society; 2015 Jul 10;1(7):285–287. PMID: 27622818

Stokes: Stokes JM, et al. A Deep Learning Approach to Antibiotic Discovery. Cell. 2020 Feb 20;180(4):688-702.e13. PMCID: PMC8349178

## Leveraging lots of data

E. coli activity data is available on >1M compounds

- ArrePath has collected a large *E. coli* activity dataset, but there is even more public data
- These are measured in different strains and assay conditions → can't compute an MIC or a percentage inhibition
- Instead, train a model that can consistently rank each assay by activity

## Antibacterial activity ranking models outperform single task classification models

- ArrePath has trained a multitask ranking model that predicts antibacterial activity. It is trained on 1.1M compounds across 9 datasets including WT, efflux deficient, and membrane compromised strains.
- Single task models trained on our internal permeabilized mutant data or a WT Pubchem screen perform well on the datasets they are trained on but generalize poorly to new data.
- The ranking model performs equivalently to the single task models on the data they are trained on and *better* on other datasets.

For classification training datasets: hold out 1/5<sup>th</sup> of data as test set and hold out all scaffolds in test set from training data. For all other datasets, hold out entire dataset as test set.

## **Ranking model enriches for hits in early selection**

#### Enrichment factors up to 20x: 20% of actives identified after screening 1% of library

## Cytotoxicity ranking models outperform single task classification models

A

- ArrePath has trained a multitask ranking model that predicts cytotoxicity. It is trained on 2M compounds across 16 datasets, including measurements on HepG2, HEK293, and three other cell lines
- As in antibiotic activity, single task models perform well on the datasets they are trained on but generalize poorly to new data.
- The ranking model performs equivalently to the single task models on the data they are trained on and *better* on other datasets.

For training datasets: hold out 1/4<sup>h</sup> of data as test set and hold out all scaffolds in test set from training data.

### **Compound selection strategy**

#### Source compounds from Enamine screening collections

- Excluding compounds structurally similar to any antibiotic approved or tested in the clinic.
- Pick compounds to maximize the distance from the cytotoxicity-antibacterial activity tradeoff boundary.
- We limit how many structurally similar compounds are selected to maximize diversity.
- Compounds are screened in *E. coli lptD* in M9 media in single replicates, followed by triplicate confirmation of hits.
- We also selected several pre-plated sets with high fractions of predicted actives.

### ArrePath's antibiotic activity model enriches for screening hits

2x increase in hit rate over unguided screening plus focus on tractability

- ML-guided cherry-picking yielded twice as many hits as unguided selection, while selecting for low cytotoxicity and maximizing diversity
- Quality of hits improved significantly fewer weak inhibitors

## ArrePath's ML-guided screening enriches for progressible hits

*3x reduction in cytotoxic molecules over unguided screening* 

- 13% of ML-selected hits "fail" due to cytotoxicity (cytotoxicity window <2)</li>
- 37% of non-selected hits "fail" due to cytotoxicity
- This represents an additional enrichment in progressible hits. Combined with the ~2x enrichment in hits, this yields a ~3x efficiency gain in progressible hits from ML-guided screening
- Compounds which do pass are on average less toxic (median cytotoxicity window 10 vs 6)
- We identify a larger fraction of WT-active compounds in ML-guided screening (67% vs 45%)

### ArrePath's ML-guided screening identifies chemically-diverse hits

A

- The chemical space covered by our hits is distinct from both clinically used antibiotics and published non-clinical antibacterials
- The plot on the right shows a tmap projection of our screened chemical space along with our hits, clinical antibiotics, and antibacterials

- ArrePath ML-guided hits
- All screened compounds
- Approved antibiotics
- Non-clinical antibacterials of known mechanism

- Multiple ML models have been shown to yield high hit rates for predicting antibacterial activity
- These are reported on testing a small number of topranked compounds which increases hit rate
- Additionally, they frequently include compounds highly similar to known antibiotics (e.g. 47/51 for Stokes)
- We estimate a hit rate in a similar range if we tested only the top ranked hits in our screen

\*Estimated

Sources: PowerPoint Presentation (roche.com);

 Instead, we aim to prioritize selection of compounds with novel MoAs that can progress to hit-to-lead efforts

Stokes JM, et al. A Deep Learning Approach to Antibiotic Discovery. Cell. 2020 Feb 20;180(4):688-702.e13.

Source	Model	Compounds Tested	Hit Rate
Roche	GNEprop	345	24%
Stokes	Chemprop	99	51%
ArrePath*	Ranking	345	32%

#### Mechanistically novel hits are identified with ArrePath's imaging platform

All screening hits are profiled on our imaging platform to predict mechanistic novelty and potential targets

50

**ARREPATH** 

#### Example hits shown below

- 104,779 compounds screened: ~30,000 cherry picked; ~70,000 in pre-plated libraries
- 3,376 primary hits; 1001 selected for follow up
- 287 active in in-house dose-response
- Example compounds:

AP-00471778 MIC: 4 μg/mL (*E. coli* lptD, M9 media)

Putative target: Val/IIe Biosynthesis AP-00469177 MIC: 1 μg/mL (*E. coli* ATCC25922, M9 media)

> Putative target: Uracil Biosynthesis

AP-00477607 MIC: 8 μg/mL (*E. coli* ATCC25922, M9 media)

> Putative target: Cysteine Biosynthesis

All three compounds show no HepG2 cytotoxicity at 100  $\mu M$ 

- Predictive antibacterial models can be trained from data across multiple bacterial assays, including across strains and media
- Screening compounds selected by antibacterial and cytotoxicity models increases antibacterial hit rate by 2x, and reduces cytotoxicity failures by 3x
- Screening compounds selected by antibacterial models increases wild type hit rate by 1.5x, indicating the models learn features associated with permeability and efflux avoidance
- Screening hits are prioritized by mechanistic novelty using imaging
- ArrePath has used these approaches to identify a chemically diverse set of antibacterials active against multiple novel targets, resulting in our current LO project and another HTL project.
